Who I would build DocShield AI with

Selection logic

I did not pick the strongest engineers I know. I picked the three people who close the three weaknesses the 72-hour build actually exposed.

Gaps the prototype revealed — each one observed, not imagined

Usability A qualified engineer read an absence of detected anomalies as the document being *"certified and trustworthy"*. The analysis was correct; the reading was not. A screening tool that misleads its own user fails.
Fraud expertise An AI-generated invoice scored low risk, and a coherent fabrication still passes every check. Knowing which fraud patterns matter, and what a false positive costs against a miss, is domain knowledge I do not have.
Production No rate limiting, a payload ceiling on the host, no persistence. The prototype runs; it is not yet a service.

1. Product and user experience

Mohamed-Sadik Derbi · Software Engineer, product and UX

Contact +212 651 843 140 · linkedin.com/in/mohamed-sadikderbi
Key capability Product thinking, UX/UI design, full-stack development.
Why him DocShield produces a correct analysis that a reviewer can still misread — deliverable 03 records exactly that happening. Turning a risk score into a decision someone trusts is a product problem, not a model problem, and it is the part I am weakest on. He has reviewed the prototype himself, so he starts from what it does rather than from a brief.
Role Design the verification workflow, the evidence presentation and the reviewer's decision path.
Potential He works across product and engineering, so he can argue with the constraint instead of designing around it. That combination is rare, and it is what turns a technical result into a usable one.

2. Fraud and security

Abderrazak Hajji · Cybersecurity / Fraud Specialist

Contact +212 620 671 238 · linkedin.com/in/abderrazak-hajji-45a2132bb
Key capability Cybersecurity, threat analysis, fraud detection.
Why him My tests proved the system misses well-made forgeries. Deciding which fraud patterns to prioritise, and where a false positive costs more than a miss, requires someone who has seen real fraud.
Role Define fraud scenarios, calibrate severity and the false-positive threshold, challenge the detection rules adversarially.
Potential He thinks like an attacker, which is the only reliable way to test a detection tool. Someone whose instinct is to break the system is worth more here than another builder.

3. Backend, cloud and MLOps

Adama · Backend / Cloud / MLOps Engineer

Contact +212 614 166 631 · linkedin.com/in/startlingadama
Key capability Backend engineering, DevOps, cloud infrastructure, AI systems.
Why him The prototype has no rate limiting, no persistence and a payload ceiling on its host. Each of these is a production problem, and each one blocks a first paying customer.
Role Build the API, the infrastructure and the deployment pipeline; make the system scale and stay within cost.
Potential He covers software, DevOps and AI at once — a range that usually takes three people. On a small team, that breadth is the difference between shipping and stalling.

What this team would look like

Four people covering detection, product, adversarial testing and production, with me on the AI and detection side. Deliberately no second AI engineer — the prototype's failures were never a lack of modelling: they were a lack of usability, domain knowledge and operational rigour.
